Increased Fidelity and Associated Computational cost of Detailed Integral Experiment Benchmarks

Zach Lemke

July 8, 2025

The CERBERUS Integral Experiment

- “Critical Experiment Reflected By copper to bEtteR Understand Scattering”
- Designed to be particularly sensitive to Cu scattering
- “Zeus” style experiment
 - Fuel arrangement and reflector used in many previous experiments
- Fueled by the Jemima plates, 21” diameter HEU disks
- Utilized both a Cu reflector and Cu interstitial plates
- Executed August-September 2023

CERBERUS Pictures

The ICSBEP Benchmark

- International Criticality Safety Benchmark Evaluation Project
- Foremost a collection of benchmarks for criticality safety
- Used by nuclear data adjusters
- Validates differential measurements
- “Section 2” of the ICSBEP Benchmark focuses on uncertainty quantification
- Requires a plethora of perturbations to parts
 - Masses, compositions, dimensions, positioning
- Used to determine the effect of each uncertainty on the overall criticality measurement

Section 2 of CERBERUS

- Over 1000 simulations were performed for Section 2 of CERBERUS
 - Add even more considering reruns
 - Totaled ~305k computer hours as given by the MCNP output
- This is a notable increase from other Zeus benchmarks
- Why?
 - Desire to see the effect of each individual part
 - “Minimal” effort increase utilizing python

Example: Diameter and Alignment of HEU Interstitial

- HEU modeled as perfectly aligned with nominal dimensions
- Clearly not the case
- Does this matter?
- Need to simulate to find out

How is CERBERUS Different?

- Traditionally, all Jemima plate diameters would be perturbed at the same time
- For CERBERUS, each Jemima plate diameter was perturbed individually
- Allowed for the investigation of the sensitivity of the system to each specific item of fuel
- Accomplished utilizing python scripting (see my talk from last year)
 - Required more upfront effort, but designed to be applicable to other Zeus-like configurations
- Required significantly more computational resources
 - Whether this is justified is likely use-case dependent

Summary of Results

- It does not seem like the system is significantly more sensitive to diameters of components near the center of the core
 - Intuitively it is, but was not detectable with simulations run to a Monte Carlo k_{eff} uncertainty of 0.00002
- The system is more sensitive to heights of components near the center of the core
 - Most (if not all) Zeus style benchmarks have perturbed core component heights individually

Acknowledgments

This work was supported by the US Department of Energy through the Los Alamos National Laboratory. Los Alamos National Laboratory is operated by Triad National Security, LLC, for the National Nuclear Security Administration of the US Department of Energy under Contract No. 89233218CNA000001.
